VERDIGRIS BASIN TOTAL MAXIMUM DAILY LOAD

Waterbody: Verdigris River
Water Quality Impairment: Fecal Coliform Bacteria

1. INTRODUCTION AND PROBLEM IDENTIFICATION

Subbasin: Upper Verdigris  County: Montgomery

HUC 8: 11070103

HUC 11 (HUC 14s): 010 (030 and 090)

Drainage Area: 82 square miles

Main Stem Segments: WQLS: 29, 33 and 35 (Verdigris River) starting at confluence with Pumpkin Creek and traveling upstream to central Montgomery County (Figure 1).

Tributary Segment: WQLS: Rock Creek (58)

Designated Uses: Special Aquatic Life Support, Primary Contact Recreation, Domestic Water Supply; Food Procurement; Ground Water Recharge; Industrial Water Supply Use; Irrigation Use; Livestock Watering Use for Main Stem Segments (29, 33 and 35).

Expected Aquatic Life Support and Secondary Contact Recreation on Tributary Segment 58 (Rock Creek)

1998 303(d) Listing: Table 1 - Predominant Non-point Source and Point Source Impacts

Impaired Use: Contact Recreation

Water Quality Standard: 200 colonies per 100 ml (geometric mean) for Primary Contact Recreation in April-October (K.A.R. 28-16-283(c)(7)(B)); 2,000 colonies per 100 ml for Secondary (KAR 28-16-28e(c)(7)(C))

2. CURRENT WATER QUALITY CONDITION AND DESIRED ENDPOINT

Level of Support for Designated Use under 1998 303(d): Not Supporting Contact Recreation

Monitoring Sites: Station 563 near Independence
Period of Record Used: 1990 - 2000 for Station 563 (Figure 2)

Flow Record: Verdigris River at Independence (USGS Station 07170500)

Long Term Flow Conditions: 10% Exceedance Flows = 7,270 cfs, 95% = 23.1 cfs
Current Conditions: Since loading capacity varies as a function of the flow present in the stream, this TMDL represents a continuum of desired loads over all flow conditions, rather than fixed at a single value. Sample data for the sampling site were categorized for each of the three defined seasons: Spring (Apr-Jul), Summer-Fall (Aug-Oct) and Winter (Nov-Mar). High flows and runoff equate to lower flow durations; baseflow and point source influences generally occur in the 75-99% range. A Load curve was established for the Secondary Contact Recreation criterion by multiplying the flow values along the curve by the applicable water quality criterion and converting the units to derive a load duration curve of colonies of bacteria per day. This load curves represent the TMDL since any point along the curve represents water quality for the standard at that flow. Historic excursions from the water quality standard are seen as plotted points above the load curve. Water quality standards are met for those points plotting below the load duration curve (Figure 5).

At least one excursion was seen in each of the three defined seasons and these exceedances are outlined in Table 1. Five percent of Spring samples and 11% of the Summer-Fall samples were over the secondary contact criterion. Nine percent Winter samples were over the secondary criterion. Overall, 8% of the samples were over the criteria. This would represent a baseline condition of full support of the impaired designated use.

Desired Endpoints of Water Quality (Implied Load Capacity) at Site 563 over 2007 - 2011

The ultimate endpoint for this TMDL will be to achieve Kansas Water Quality Standards which fully support both Primary Contact Recreation and Secondary Contact Recreation. This TMDL will, however, be phased. Kansas has a Primary Contact Recreation standard of a geometric mean of 200 colonies per 100 ml taken from at least five samples taken within a 30-day period. Kansas monitoring protocols do not collect data to evaluate compliance with the five-sample geometric mean criterion. The geometric mean of all samples taken from the Verdigris River in April through October over 1990-2001 was 132 colonies per 100 ml. The more recent geometric mean taken over 1996-2001 was 82 colonies per 100 ml, indicating that major excursions may have been associated with the higher flow conditions prior to 1996.

Conversely, the Secondary Contact Recreation standard is measured by a single “not to exceed” criterion of 2000 colonies per 100 ml. This criterion was used to establish a Phase One load duration curve shown in Figure 5. A corresponding load curve for the geometric mean of 200 colonies is also shown in Figure 5 as a reference. It is recognized, however, that the Primary and Secondary Contact Recreation criteria will be revised in the future in accordance with national guidance, notably changing the indicator from fecal coliform to *E. coli*. Both geometric mean and single value criteria are expected to be developed. A revised Primary Contact Recreation TMDL curve will be established in Phase Two of this TMDL to reflect changes in this Standard. For Phase One the endpoint will be to maintain the Secondary Contact Recreation value of 2,000 colonies per 100 ml represented by the load curve shown as the Phase One TMDL figure (Figure 5). Monitoring data plotting below the TMDL curve will indicate attainment of the water quality standards.

This endpoint will be reached through the maintenance of current loadings from the various sources in the watershed. Achievement of the endpoint indicates loads are still within the loading capacity of the stream, water quality standards continue to be attained and full support of the designated uses of the stream has been upheld.
3. SOURCE INVENTORY AND ASSESSMENT

NPDES: There is one NPDES permitted wastewater discharger to the Verdigris River immediately upstream of the watershed (Figure 3). This system is outlined below in Table 2. The Park West Properties facility has a non-discharging lagoon that may contribute a bacteria load to Segment 58 of Rock Creek under extreme precipitation events (stream flows associated with such events are typically exceeded one 1 - 5 % of the time). Such events would not occur at a frequency nor a duration that they would constitute a chronic impairment to the designated uses of the river. All non-discharging lagoon systems are prohibited from discharging to the surface waters of the state. Under standard conditions of these non-discharging facility permits, when the water level of the lagoon rises to within two feet of the top of the lagoon dikes, the permit holder must notify KDHE. Steps may be take to lower the water level of the lagoon and diminish the probability of a bypass of sewage during inclement weather. Bypasses may be allowed if there are no other alternatives and 1) it would be necessary to prevent loss of life, personal injury or severe property damage; 2) excessive stormwater inflow or infiltration would damage the facility; or 3) the permittee has notified KDHE at least seven days before the anticipated bypass. Any bypass is immediately report to KDHE.

The city of Independence relies on a three cell lagoon system with 120 day detention times for treatment of their wastewater. Kansas Implementation Procedures - Waste Water Permitting - indicates this lagoon meets standard design criteria which have been shown to consistently meet or exceed the bacteria standard. A mechanical system is under construction with UV disinfection to adhere to bacteria permit limits.

NPDES facilities on other tributaries upstream of the impaired segments covered by this TMDL, have bacteria limits in place with treatment controls, or use lagoons which comply with state design standards and adequately treat bacteria.

The population projection for Independence to the year 2020 indicate moderate declines. Projections of future water use and resulting wastewater appear to be within the design flows for the current and proposed system’s treatment capacity. At site 563, excursions from the water quality standards appear to occur under runoff or higher flow conditions. Of significance to point sources are the lack of excursions under low flow in all seasons, especially during winter, therefore point sources are not seen as a significant cause of water quality violations in the watershed.

Figure 3
Livestock Waste Management Systems: Nine operations are registered, certified or permitted within the watershed. These facilities (mostly swine or beef facilities) are evenly distributed across the watershed (Figure 3). Permitted livestock facilities have waste management systems designed to minimize runoff entering their operations or detaining runoff emanating from their areas. Such systems are designed to retain the 25 year, 24 hour rainfall/runoff event, as well as an anticipated two weeks of normal wastewater from their operations. Such rainfall events typically coincide with stream flows which are exceeded less than 1 - 5 percent of the time. Therefore, events of this type, infrequent and of short duration, are not likely to cause chronic impairment of the designated uses of the waters in this watershed. Requirements for maintaining the water level of the waste lagoons a certain distance below the lagoon berms ensures retention of the runoff from these intense, local storm events. In Montgomery County, such an event would generate 6.8 inches of rain, yielding 5.6 to 6.4 inches of runoff in a day.

NPDES permits, also non-discharging, are issued for facilities with more than 1,000 animal units. None of the facilities in the watershed are of this size. Potential animal units within the watershed for all facilities is 3,776. The actual number of animal units on site is variable, but typically less than potential numbers.

Land Use: Most of the watershed is grassland (52% of the area), cropland (33%), or woodland (8%). The cropland appears to be located along the main stem or in the Rock Creek subwatershed. The grazing density estimate is average for the watershed when compared to densities elsewhere in the Verdigris Basin (33-42 animal units/mi²) (Figure 4).

On-Site Waste Systems: The watershed’s population density is high when compared to densities across the Verdigris Basin (46-204 person/mi²) (Figure 4). The rural population projection for Montgomery county through 2020 shows modest growth (10% increase). Based on 1990 census data, almost 3,700 households in Montgomery county are on septic systems. Failing on-site waste systems can contribute bacteria loadings, and their impact on the impaired segments may be a source of interest to the watershed, given the population density of the watershed.

Background Levels: Some fecal bacteria counts may be associated with environmental background levels, including contributions from wildlife, but it is likely that the density of animals such as deer is fairly dispersed across the watershed resulting in minimal loading to the river below the levels necessary to violate the water quality standards.

Land Use, Population and Grazing Density

Figure 4
4. ALLOCATION OF POLLUTION REDUCTION RESPONSIBILITY

The nature of bacteria loading is too dynamic to assign fixed allocations for wasteloads and non-point loads. Instead, allocation decisions will be made which reflect the expected reduction of bacteria loading under defined flow conditions. These flow conditions will be defined by the presumed ability of point or non-point sources to be the dominant influence on stream water quality. Therefore, the allocation of wasteloads and loads will be made by demarcating the seasonal TMDL curves at a particular flow duration level. Flows lower than that designated flow will represent conditions which are the responsibility of point sources to maintain water quality standards, those flows greater than the designated flow are the responsibility of non-point sources.

**Point Sources:** The city of Independence presently relies on a lagoon system with long detention times for treatment of their wastewater. Their proposed mechanical, 3.0 mgd design flow system will utilize UV disinfection to minimize bacteria stream loads. Point sources are responsible for maintaining their systems in proper working condition and appropriate detention volume to handle anticipated wasteloads of their respective populations. NPDES permits have been reissued for all of the discharging facilities in 2001. The Phase One Wasteload Allocations based on the proposed upgrade to the city of Independence facility will be defined as the product of the 2,000 count bacteria criteria and flows occurring 84-99% of the time (Figure 5). Wasteload allocations are established for the low flows conditions which are most susceptible to impact from point source discharges. Typically, these conditions are deemed to be ten times the combined design flow of the facilities or the 7Q10, whichever is greater. This allocation accounts for future point source loads exerting some impact on the water quality of the stream.

The non-discharging lagoon system of the Park West Properties facility is prohibited from discharging their wasteloads, therefore their Wasteload Allocations are zero. State permitted non-discharging livestock waste management facilities will also have a Wasteload Allocation of zero, given that these facilities will not discharge to receiving streams throughout the majority of hydrologic conditions, defined by the curve ranging from 5 to 100 percent of the time. Depending on the areal extent of the storm creating a 25 year, 24 hour precipitation event, the associated stream flows would be exceed less than 1 - 5 percent of the time.

Given the large contributions from both the CAFO bypass and non-point sources, substantial reductions would be necessary. There is a need to maintain zero discharge from CAFOs or state permitted facilities to protect water quality, but under extreme high flow conditions, the ability to retain all the runoff from these feeding areas is hydrologically exceeded. Additionally, the ability of Best Management Practices to reduce non-point source contributions under these conditions to levels where the TMDL might be met is elusive. Fortunately, the frequency of such events is low and their duration short, because of the passing of the high flow crest. Recreation use of the stream is unlikely under these extreme high flow conditions.

Any future NPDES and state permits will be conditioned such that discharges from the permitted facilities will not cause violations of applicable criteria below the flows amenable to respond to management practices. Ongoing inspections and monitoring of these systems will be made to ensure that minimal contributions have been made by these sources.
Non-Point Sources: Based on the assessment of sources, the distribution of excursions from water quality standards and the relationship of those excursions to runoff conditions, non-point sources are seen as a significant cause of the water quality violation. Background levels are not a significant cause of the problem. Implementation of non-point source pollution control practices should be taken within one mile of the listed stream segments.

Activities to reduce fecal pollution should be directed toward the smaller, unpermitted livestock operations and rural homesteads and farmsteads along the river. The Load Allocation assigns responsibility for maintaining water quality below the TMDL curve over flow conditions exceeded 84% of the time (greater than 46 cfs streamflow) (Figure 5). Best Management Practices will be directed toward those activities such that there will be minimal violation of the applicable bacteria criteria at higher flows.

Definition Margin of Safety: Because there will not be a traditional load allocation made for fecal bacteria, the margin of safety will be framed around the desired endpoints of the applicable water quality standards. Therefore, evaluation of achieving the endpoints should use values set 100 counts less than the applicable criteria (1,900 colonies for secondary contact recreation) to mark full support of the recreation designated use of the streams in this watershed. By this definition, the margin of safety is 100 colonies per 100 ml and would be represented by a parallel line lying below the TMDL curve by a distance corresponding to loads associated with 100 colonies per 100 ml.

State Water Plan Implementation Priority: Because the frequency of excursions from the water quality standard is presently less than 10% of samples, this TMDL will be a Medium Priority for implementation.
Unified Watershed Assessment Priority Ranking: This watershed lies within the Middle Verdigris Basin (HUC 8: 11070103) with a priority ranking of 26 (Medium Priority for restoration work).

Priority HUC 11s and Stream Segments: Unless impairment is determined by additional monitoring between 2003-2007, no priority HUCs or stream segments will be identified.

5. IMPLEMENTATION

Desired Implementation Activities

1. None, unless impairment is determined by additional monitoring between 2003-2007.

Implementation Programs Guidance

Unless impairment is determined by additional monitoring between 2003-2007, no direction is needed on implementation programs.

Time frame for Implementation: Conditions will be evaluated based additional on monitoring between 2003-2007.

Targeted Participants: None, until 2007 evaluation.

Milestone for 2007: The year 2005 marks the midpoint of the ten-year implementation window for the watershed. At that point in time, additional monitoring data from Station 563 will be reexamined to confirm the impaired status of the streams within this watershed. Should the case of impairment develop, source assessment, allocation and implementation activities will ensue.

Delivery Agents: None at this time. Status will be re-evaluated in 2007.

Reasonable Assurances:

Authorities: The following authorities may be used to direct activities in the watershed to reduce pollution.

1. K.S.A. 65-164 and 165 empowers the Secretary of KDHE to regulate the discharge of sewage into the waters of the state.

2. K.S.A. 65-171d empowers the Secretary of KDHE to prevent water pollution and to protect the beneficial uses of the waters of the state through required treatment of sewage and established water quality standards and to require permits by persons having a potential to discharge pollutants into the waters of the state.

3. K.A.R. 28-16-69 to -71 implements water quality protection by KDHE through the establishment and administration of critical water quality management areas on a watershed basis.
4. K.S.A. 2-1915 empowers the State Conservation Commission to develop programs to assist the protection, conservation and management of soil and water resources in the state, including riparian areas.

5. K.S.A. 75-5657 empowers the State Conservation Commission to provide financial assistance for local project work plans developed to control non-point source pollution.

6. K.S.A. 82a-901, et seq. empowers the Kansas Water Office to develop a state water plan directing the protection and maintenance of surface water quality for the waters of the state.

7. K.S.A. 82a-951 creates the State Water Plan Fund to finance the implementation of the Kansas Water Plan.

8. The Kansas Water Plan and the Verdigris Basin Plan provide the guidance to state agencies to coordinate programs intent on protecting water quality and to target those programs to geographic areas of the state for high priority in implementation.

**Funding:** The State Water Plan Fund, annually generates $16-18 million and is the primary funding mechanism for implementing water quality protection and pollution reduction activities in the state through the Kansas Water Plan. The state water planning process, overseen by the Kansas Water Office, coordinates and directs programs and funding toward watersheds and water resources of highest priority. Typically, the state allocates at least 50% of the fund to programs supporting water quality protection. This watershed and its TMDL is a Medium Priority consideration.

**Effectiveness:** Improvements in reducing bacteria loading to streams can be accomplished through appropriate management and control systems for livestock waste and on-site waste systems.

**6. MONITORING**

KDHE will continue to collect bimonthly samples during 2003 at rotational Station 563, over each of the three defined seasons. Based on that sampling, the priority status of 303(d) listing will be evaluated in 2006. Should impaired status remain, the desired endpoints under this TMDL will be refined and direct more intensive sampling may need to be conducted under specified seasonal flow conditions over the period 2007-2011. The manner of evaluation will be consistent with the assessment protocols used to establish the case for impairment in these streams. Following current (1998) Kansas assessment protocols, monitoring will ascertain if less than 10% of samples exceed the applicable criterion at flows under 7,230 cfs with no samples exceeding the criterion at flows under 2,480 cfs. Use of the real time flow data available at the Verdigris River at Independence stream gaging station can direct sampling efforts.

Monitoring of bacteria levels in effluent will be a condition of NPDES and state permits for facilities. This monitoring will continually assess the functionality of the systems in reducing bacteria levels in the effluent released to the streams.
7. FEEDBACK

Public Meetings: Public meetings to discuss TMDLs in the Verdigris Basin were held January 23 in Fredonia and March 6, 2002 in Neodesha. An active Internet Web site was established at http://www.kdhe.state.ks.us/tmdl/ to convey information to the public on the general establishment of TMDLs and specific TMDLs for the Verdigris Basin.

Public Hearing: A Public Hearing on the TMDLs of the Verdigris Basin was held in Neodesha on June 4, 2002.

Basin Advisory Committee: The Verdigris Basin Advisory Committee met to discuss the TMDLs in the basin on October 3, 2001, January 23 and March 6, 2002.

Milestone Evaluation: In 2007, evaluation will be made as to the degree of impairment which has occurred within the watershed and current condition of Verdigris River. Subsequent decisions will be made regarding the implementation approach and follow up of additional implementation in the watershed.

Consideration for 303(d) Delisting: The stream will be evaluated for delisting under Section 303(d), based on the monitoring data over the period 2007-2011. Therefore, the decision for delisting will come about in the preparation of the 2012 303(d) list. Should modifications be made to the applicable water quality criteria during the ten-year implementation period, consideration for delisting, desired endpoints of this TMDL and implementation activities may be adjusted accordingly.

Incorporation into Continuing Planning Process, Water Quality Management Plan and the Kansas Water Planning Process: Under the current version of the Continuing Planning Process, the next anticipated revision will come in 2003 which will emphasize implementation of TMDLs. At that time, incorporation of this TMDL will be made into both documents. Recommendations of this TMDL will be considered in Kansas Water Plan implementation decisions under the State Water Planning Process for Fiscal Years 2003-2007.
